Abstract: Doxorubicin (DOX), an anthracycline antibiotic, is a broad-spectrum antineoplastic agent, which is commonly used in the treatment of uterine, ovarian, breast and lung cancers, Hodgkin's disease and soft tissue sarcomas as well as in several other cancer types. The effect of doxorubicin (4 mg/kg b.w./week) without or with oral administration of ethanolic purslane (Portulaca oleracea) shoot (leaves and stems) extract (50 mg/kg b.w./day) or ethanolic purslane seeds extract (50 mg/kg b.w./day) co-treatments for 6 weeks was evaluated in adult male rats. Serum ALT, AST, ALP, GGT, total bilirubin, total protein and albumin levels were assayed. Lipid peroxidation (indexed by MDA) and antioxidants like hepatic glutathione, glutathione transferase, peroxidase, superoxide dismutase and catalase were assessed. There was an increase in serum levels of ALT, AST, ALP, GGT and total bilirubin. In addition, hepatic glutathione, glutathione transferase, peroxidase, superoxide dismutase and catalase activities were decreased while lipid peroxidation in the liver was increased. Co-administration of ethanolic purslane shoot and seed extracts successfully improved the adverse changes in the liver functions with an increase in antioxidants activities and reduction of lipid peroxidation. In conclusion, it can be supposed that dietary purslane shoot and seed extracts’ supplementation may provide a cushion for a prolonged therapeutic option against DOX hepatopathy without harmful side effects. However, further clinical studies are required to assess the safety and efficacy of these extract in human beings.

Key words: Doxorubicin, purslane, hepatotoxicity and antioxidants.

1. Introduction

Doxorubicin (DOX) obtained from soil actinomycetes Streptococcus peucetius is used for the treatment of solid tumors such as those arising in the breast, bile ducts, endometrial tissue, esophagus and liver, osteosarcomas, soft-tissue sarcomas and non-Hodgkin's lymphoma (Tikoo et al., 2011). DOX is known as a powerful anthracycline antibiotic widely used to treat many human cancers, but significant cardiotoxicity (Kuznetsova et al., 2011), hepatotoxicity (Patela et al., 2010), nephrotoxicity (Mohana et al., 2010) and testicular toxicity (Trivedi et al., 2011) limits its clinical application. Mitochondria are considered to be one of the primary targets of DOX through mitochondria-mediated apoptosis, remarkable modification of mitochondrial membranes (e.g. via binding with cardiolipin), which is also associated with changes in various mitochondrial functional parameters and activities of respiratory chain complexes (Trivedi et al., 2011). Moreover, doxorubicin significantly damages energy-transferring and -signalling systems like creatine kinase and AMP-activated protein kinase (Kuznetsova et al., 2011) Doxorubicin causes disturbances in the balance between oxidative stress and antioxidant defence system leading to tissue injuries (Saad et al., 2001; Karaman et al., 2006).

A number of studies were conducted for antioxidants screening from the natural medicine aiming to minimize oxidative injury by DOX. Several natural antioxidants have been shown to alleviate the DOX-induced cell damage without compromising its anti-tumor efficacy in the animal studies (Xin et al., 2011). Portulaca oleracea L. is commonly known as purslane. It is a warm climate, annual and green shoot (Al-Quraishy et al., 2012). Recent research indicates that purslane offers better nourishment than the major cultivated vegetables due to its shoot that is a rich source of X9-3-fatty acids, α-tocopherols, ascorbic acid, β-carotene and glutathione. Its seeds also contain a high percentage of α-linolenic acid (LNA) (Al-Quraishy et al., 2012). These features contribute to the anti-oxidative properties of purslane which derive from the following pharmacologically active substances, including: 28% flavonoids, that are nearly exclusively flavonol-O-glycosides; 8% terpenoids (principally ginkgolides A, B, C and bilobalide); 6–12% organic acids; and >0.5% proanthocyanidins defined as flavonoid-based polymers. Purslane is effective as an antioxidant agent (Dkhil et al., 2011) as well as providing nourishment for the liver, kidneys
and testes. Experimental evidence has also shown that purslane has an anti-oxidative effect in heart tissues in mice by increasing superoxide dismutase activity (Al-Quraishy et al., 2012). Other authors reported that the purslane contains many compounds, including alkaloids, omega-3 fatty acids, coumarins, flavonoids, polysaccharide, cardiac glycosides, antraquinone glycosides and containing β-sitosterol (Mohamed et al., 2011).

Based on these issues and concerns, the present study was designed to investigate the preventive effect of ethanolic extract of purslane shoot parts and seeds on liver dysfunction and oxidative stress in doxorubicin-administered rats.

2. Materials and methods

2.1. Experimental animals:

Male Wistar albino rats weighing about 140-180g were used as experimental animals in the present investigation. They were obtained from the animal house of Research Institute of Ophthalmology, El-Giza, Egypt. They were kept under observation for about 15 days before the onset of the experiment to exclude any intercurrent infection. The chosen animals were housed in plastic cages with good aerated covers at normal atmospheric temperature (25±5°C) as well as 12 hours daily normal light periods. Moreover, they were given access of water and supplied daily with standard pellet diet ad libitum. All animal procedures are in accordance with the recommendations of the Canadian Committee for Care and Use of animals (Canadian council on Animal care [CCAC], 1993).

2.2. Chemicals and drugs

Doxorubicin was purchased from EBEWE pharma, Ges. m.b.H. Nfg. KG A-4866 Unterach, Austria. Purslane shoot parts and seeds were purchased from Harraz Medicinal plant company, Cairo, Egypt (www.harrazegypt.com). Total bilirubin and ALP (alkaline phosphatase) kits were obtained from SCICO Diagnostic Company and ALT (alanine aminotransferase), AST (aspartate aminotransferase) and GGT (gamma-glutamyl transferase) kits were purchased from Quimica Clinica Aplicada S.A. Company (Spain). Albumin and total protein kits were obtained from Diamond Diagnostics, Egypt. Chemicals used in measurement of antioxidants were obtained from Sigma Chemical Company, USA.

2.3. Shoot and seed extract

The shoot parts of the plant and seeds were dried in the shade. They were powdered by an electric grinder; then, they were exhaustively extracted with 80% ethanol. The solvent was removed by evaporation under reduced pressure using Bucchi Rotary Evaporator (Wang et al., 2012).

2.4. Experimental Animal grouping and experimental design:

The animals of the present experiment were allocated into 4 groups:

1. Normal control: The rats of this group were given the equivalent volume of vehicle (0.9% NaCl ) for 45 days
2. Doxorubicin–administered control: The rats of this group were intraperitoneally administered doxorubicin at a dose of 4 mg/Kg b.w./week for 6 weeks (Trivedi et al., 2011).
3. Doxorubicin–administered group treated with purslane shoot extract: This group was intraperitoneally administered doxorubicin at a dose of 4 mg/Kg b.w./week for 6 weeks and was orally treated (by oral gavage) with purslane shoot extract at dose level of 50 mg/kg b.w./day for 6 weeks (Ali and Bashir, 1994; Fayong Gong et al., 2009).
4. Doxorubicin–administered group treated with purslane seeds extract: This group was intraperitoneally administered doxorubicin at a dose of 4 mg/Kg b.w./week for 6 weeks and was orally treated (by oral gavage) with purslane seed extract at dose level of 50 mg/kg b.w./day for 6 weeks (Ali and Bashir, 1994; Fayong Gong et al., 2009).

2.5. Preparation of blood and tissue homogenates

By the end of the experimental periods (6 weeks), rats were scarified under mild diethyl ether anesthesia at fasting state. Blood samples were collected and allowed to coagulate at room temperature. The clear, non-haemolysed supernatant sera were quickly removed and divided into four portions for each individual, and stored at - 20˚ C for subsequent analysis. Liver was quickly excised, weighed and homogenized in a saline solution (0.9 %NaCl) (10% w/v) using Teflon homogenizer (Glas-Col, Terre Haute, USA). The homogenates were centrifuged at 3000 r.p.m. for 15 minute and the supernatants were kept at -20˚ C for the assay of biochemical parameters related to oxidative stress and antioxidant defense system.

2.6. Assay of liver function parameters:

ALT and AST activities in serum was determined according to the method of Reitman and Frankel (1957) using reagent kits purchased from Quimica Clinica Aplicada S. A. Company (Spain). GGT activity was measured according to the method of Szasz (1969) using reagent kits obtained from Quimica Clinica Aplicada S. A. Company, (Spain). ALP activity was measured according to the method of Kind and King (1954) by using reagent kits obtained from SCICO Diagnostic Company, Egypt. Total bilirubin concentration in serum was determined in serum according to the method of Jendrassik and Grof.
Liver oxidative stress and antioxidant defense parameters were estimated using chemicals purchased from Sigma Chemical Company (USA) and using Jenway Spectrophotometer (Germany). Glutathione activity in homogenates was determined according to the chemical method of Beutler et al. (1963) with little modification. Lipid peroxidation in homogenates was determined according to the chemical method of Preuss et al. (1998). Peroxidase (POX, EC 1.11.1.7) activity in homogenates was estimated according to the modified chemical method of Kar and Mishra (1976). Superoxide dismutase (SOD, EC 1.15.1.1) activity in homogenates was determined according to the chemical method of Marklund and Marklin (1974). Glutathione-S-transferase (GST, EC 2.5.1.18) concentration in homogenates was determined according to the chemical method of Mannervik and Guthenberg (1981). Catalase (CAT, EC 1.11.1.6) activity in homogenates was assayed according to the chemical method of Cohen et al. (1970).

2.8. Histological examination:
After sacrifice and dissection at specific time intervals, pieces of liver from all groups were immediately removed from each animal, fixed in 10% neutral buffered formalin and transferred to Department of Histopathology, Faculty of Veterinary Medicine, Beni-Suef University, Egypt for preparation, sectioning and staining with haematoxylin and eosin (H&E) (Bancroft and Stevens, 1982).

2.9. Statistical analysis:
The data in the present study were analyzed using the one-way analysis of variance (ANOVA) (PC-STAT, University of Georgia, 1985) followed by LSD test to compare various groups with each other. Results were expressed as mean ± standard error (SE) and values of P>0.05 were considered non-significantly different, while those of P<0.05 and P<0.01 were considered significantly and highly significantly different, respectively.

3. Results
3.1. Biochemical effects
The doxorubicin-administered rats showed a highly significant increase (P < 0.01) in serum ALT, AST, GGT and ALP activities as compared to normal control group. The treatment of doxorubicin-administered rats with purslane shoot and seed ethanolic extracts induced a highly significant decrease of the elevated serum of ALT, AST, GGT and ALP (P < 0.01) activities as compared to doxorubicin-administered rats (Table1).

The doxorubicin-administered rats showed a highly significant increase (P < 0.01) in serum level of total bilirubin concentration as compared to normal control group. The treatment of doxorubicin-administered rats with purslane shoot and seed ethanolic extracts induced a highly significant decrease of the elevated serum total bilirubin (P < 0.01) level as compared to doxorubicin-administered rats (Table 2).

The doxorubicin-administered rats showed a highly significant decrease (P < 0.01) in serum level of total protein, albumin and globulin levels as compared to normal control group. The treatment of doxorubicin injected rats with purslane shoot ethanolic extract induced a significant increase of the serum total protein, albumin and globulin (P < 0.05) level. The treatment of doxorubicin-administered rats with purslane seeds ethanolic extracts induced a highly significant increase (P < 0.01) of serum total protein, albumin and globulin as compared to doxorubicin-administered rats (Table 2).

Lipid peroxidation exhibited a highly significant increase in doxorubicin-injected rats as compared to normal rats; the recorded percentage increase was 146.50. Liver peroxidation was profoundly (P < 0.01) improved in doxorubicin-administered rats treated with purslane shoot and seed extracts recording percentage decreases of -41.73 and 58.92 respectively. The liver antioxidants levels of glutathione, catalase, SOD, peroxide and glutathione-S-transferase in doxorubicin-administered rats showed a highly significant decrease (P < 0.01) recording percentage decreases of -68.49, -86.71, -168.51, -39.72 and -47.32 respectively as compared to normal control group. The treatment of doxorubicin-administered rats with purslane shoot ethanolic extract induced a highly significant increase of the serum glutathione, catalase, SOD, peroxide and glutathione-S-transferase levels (P < 0.01); the recorded percentage increases were 83.89, 222.61, 98.31, 30.12 and 44.32% respectively as compared to doxorubicin-administered rats. The treatment of doxorubicin-administered rats with purslane seeds ethanolic extracts induced a highly significant increase (P < 0.01) in serum glutathione, catalase, SOD, peroxide and glutathione-S-transferase activities (P < 0.01) recording percentage increases of 141.89, 548.61, 121.91, 58.92 and 75.82 % respectively as compared to doxorubicin-administered rats. In general, the seed extract seemed to be the most potent in improving liver function and antioxidant defense system (Table 3).

3.2. Histological changes

The liver consists of numerous hepatic lobules (classical lobules) and connective tissue in between. However, these septae are not conspicuous so as to the liver sinusoids appear continuous from one lobe to another. Despite these differences, the portal veins, hepatic arteries and bile ductile are visible in the portal triads between lobules. The hepatocytes are arranged in hepatic strands radiating from the central vein. The hepatic sinusoids are found between hepatic strands. Kupffer cells are located inside the sinusoids.

The normal liver histological architecture is shown in figure 1 depicted part of hepatic lobules with central vein and hepatic strands radiating from central vein to the periphery enclosing sinusoids in between and kupffer cell within sinusoids.

![Figure 1: Photomicrograph of liver section showing normal rats histological architecture. Central vein (CV), hepatic strands (hs), sinusoids (s) and kupffer cells (KP) are noticed.](image1)

The liver of doxorubicin-administered rats showed many histological perturbations and deleterious changes. The photomicrographs (Figures 2a, 2b and 2c) depicted congested or hyperemic hepatic portal and central veins and hepatic sinusoids. There are also mild perivascular fibrosis, fatty changes, kupffer cell multiplication and hemorrhages. A large numbers of hepatocytes showed vascular degeneration and had a peripheral distribution within the hepatic lobules and there was hyperplasia of the bile ducts (Figures 2a, 2b and 2c). In the portal area, there are a mononuclear filtration and peri-hepatic portal vein cirrhosis (Figure 2a).

![Figure 2: Photomicrograph of liver section of doxorubicin administered rats showing fatty change (FC), perivascular fibrosis (PVF), congested portal vein (CPV) and bile ductules (bd) proliferation as well as hemorrhage (hr),vascular degeneration (VD) and kupffer cells (kp) multiplications (Figures 2 a, b and c).](image2)
The treatment of doxorubicin-administered rats with purslane shoot extract produced marked improvement of liver histological changes. Mild vascular changes and kupffer cell multiplication were noticed in liver of doxorubicin-administered rats which were treated with purslane shoot ethanolic extract (Figures 3a & 3b).

Figure 3: photomicrograph of liver section doxorubicin administered rats treated with purslane shoot ethanolic extracts showing moderate vascular changes (MVC) and kupffer cells (kp) proliferation (Figures 3a and 3b).

The treatment of doxorubicin-administered rats with purslane seed extract produced marked amendment of liver histological perturbations produced by doxorubicin. The treatment with seed extract seemed to be more potent than shoot extract. However, there are still congested hyperemic central vein and kupffer cells polifiration in liver section of doxorubicin-administered rats treated with purslane seed extracts (Figures 4a & 4b).

Figure 4: photomicrograph of liver section doxorubicin administered rats treated with purslane seed ethanolic extracts showing congested central vein (ccv) (figure 18 a), kupffer cells (kp) multiplication and hydropic cells (hc) (Figures 4a and 4b).

4. Discussion
Doxorubicin, a quinone-containing anthracycline antibiotic, is an important agent against a wide spectrum of human neoplasms. However, its toxicity limits usage in cancer chemotherapy (Singal et al., 1987; Fadillioglu et al., 2003). It has been shown that free radicals are involved in doxorubicin-induced toxicities (Yagmurca et al., 2004). The chemical structure of doxorubicin causes the generation of free radicals and the induction of oxidative stress that
correlates with cellular injury (Saad et al., 2001). Doxorurubicin causes an imbalance between free oxygen radicals (ROS) and antioxidants. The disturbance in oxidant–antioxidant systems results in tissue injury that is demonstrated with lipid peroxidation and protein oxidation in tissue (Karaman et al., 2006).

The present study revealed that intraperitoneal injection of 4 mg doxorubicin/ kg b.w. for 6 weeks induced hepatotoxicity manifested biochemically by a significant increase of serum ALT, AST, ALP and GGT activities and bilirubin concentration in addition to a significant decrease in serum total protein, albumin and globulin levels. These results are in accordance with Injac et al. (2008) who attributed the increase in the serum enzyme levels to their increased leakage from damaged and necrotic hepatocytes as a result of toxicity. El-Maraghy et al. (2009) attributed alteration in serum protein to changes in protein and free amino acids and their synthesis in the injured liver cells and/or increased protein degradation.

The increase in serum total bilirubin may be owing to blockage of bile ductules as a result of the inflammation and fibrosis in the portal triads and/or due to regurgitation of conjugated bilirubin from the necrotic hepatocytes to sinusoids (Ahmed, 2001).

The previous deleterious biochemical alterations of the present study were associated with a marked elevation of liver lipid peroxidation and a significant decrease of non-enzymatic antioxidant (glutathione) content and enzymatic antioxidants (catalase, superoxide dismutase, peroxidase and glutathione-S-transferase) enzyme activities. These results are in agreement with many other authors (Abd El-Aziz et al., 2001; Kalender et al., 2005; Yagmurca et al., 2007) who stated that one of the most prevailing hypothesis of hepatic damage from doxorubicin administration is the ability of the drug to produce reactive oxygen species (ROS) and suppress antioxidant defense mechanism. They also revealed that the increased lipid peroxidation play a critical role in liver injury.

Histopathological examination of liver sections of doxorubicin-administration rats supported the previous biochemical results. The liver exhibited fatty changes, vascular and hydroptic degeneration, perivascular fibrosis, necrosis of some hepatocytes, haemorrhage, kupffer cell multiplication and bile ductule proliferation. These results are in concurrence with Yagmurca et al. (2007) who noticed degradation of hepatocytes, congestion, necrosis and proliferation of bile ductules in doxorubicin-treated rats.

The treatment of doxorubicin-administered animals with purslane shoot and seed ethanolic extracts successfully improved the elevated serum ALT, AST, ALP and GGT activities and serum bilirubin concentration. The lowered serum total protein, albumin and globulin levels were potentially ameliorated in doxorubicin-administered rats treated with the tested extracts. These results are in agreement with previously published reports (Singal et al., 1987; Fadilioglu et al., 2003; Yagmurca et al., 2004 and Karaman et al., 2006). Moreover, Tawfeg (2008) reported that the purslane extract caused a significant reduction in the doxorubicin-induced toxicity in mice. Omoniyi and Mathew (2006) found that the aqueous extract of purslane potentially improved the functional status of liver as indicated by a decrease in serum activities of classical enzymes of liver function.

These ameliorations in biochemical serum parameters of liver function in the present study are associated with the improvement in liver histological changes. The seed extract seemed to be more potent than shoot parts. The liver showed moderate vascular changes as a result of shoot extract and hyperemic central vein and kupffer cell multiplication as a result of treatment with seed extract.

The improvement of liver function and integrity may be mediated via the antioxidant activity of purslane shoot and seed extracts. This is confirmed by the current study which revealed a significant decrease of lipid peroxidation and increase in CAT, SOD, peroxidase and glutathione-S-transferase activities and glutathione levels.

Conclusion

The co-administration of purslane shoot and seed ethanolic extracts potentially prevented the deleterious effects of doxorubicin on liver. The effect of seed ethanolic extract seemed to be more potent than that of shoot ethanolic extracts. This improvement effect in liver injury may be mediated via enhancement of the antioxidant defense system. However, further clinical studies on human beings are required to assess the efficacy and safety of the purslane ethanolic extracts.
